ABSTRACT

Mutations in *PTEN-induced putative kinase 1* (*PINK1*) cause a recessive form of Parkinson's disease (PD). *PINK1* is associated with mitochondrial quality control and its partial knock-down induces mitochondrial dysfunction including decreased membrane potential and increased vulnerability against mitochondrial toxins, but the exact function of *PINK1* in mitochondria has not been investigated using cells with null expression of *PINK1*. Here, we show that loss of *PINK1* caused mitochondrial dysfunction. In *PINK1*-deficient (*PINK1*^{-/-}) mouse embryonic fibroblasts (MEFs), mitochondrial membrane potential and cellular ATP levels were decreased compared with those in littermate wild-type MEFs. However, mitochondrial proton leak, which reduces membrane potential in the absence of ATP synthesis, was not altered by loss of *PINK1*. Instead, activity of the respiratory chain, which produces the membrane potential by oxidizing substrates using oxygen, declined. H₂O₂ production rate by *PINK1*^{-/-} mitochondria was lower than *PINK1*^{+/+} mitochondria as a consequence of decreased oxygen consumption rate, while the proportion (H₂O₂ production rate per oxygen consumption rate) was higher. These results suggest that mitochondrial dysfunctions in PD pathogenesis are caused not by proton leak, but by respiratory chain defects.

Introduction

Parkinson's disease (PD) is a neurodegenerative disease characterized by loss of dopaminergic neurons in the substantia nigra. Mitochondrial dysfunction has been proposed as a major factor in the pathogenesis of sporadic and familial PD (Abou-Sleiman et al., 2006). In particular, the identification of mutations in *PTEN-induced putative kinase 1* (*PINK1*) has strongly implicated mitochondrial dysfunction owing to its loss of function in the pathogenesis of PD (Valente et al., 2004). *PINK1* contains an N-terminal mitochondrial targeting sequence (MTS) and a serine/threonine kinase domain (Valente et al., 2004). *PINK1* kinase activity is crucial for mitochondrial maintenance via TRAP

phosphorylation (Pridgeon et al., 2007). Loss of *PINK1* function induces increased vulnerability to various stresses (Exner et al., 2007; Haque et al., 2008; Pridgeon et al., 2007; Wood-Kaczmar et al., 2008). However, silencing of *PINK1* has only been partial and only one study has been performed to assess mitochondrial functions in steady and artificial states with complete ablation of *PINK1* expression (Gautier et al., 2008).

Several studies have shown that *PINK1* acts upstream of parkin in the same genetic pathway (Clark et al., 2006; Park et al., 2006) and co-overexpressed *PINK1* and parkin both co-localized to mitochondria (Kim et al., 2008). Overexpression of *PINK1* promotes mitochondrial fission (Yang et al., 2008). Fission followed by selective fusion segregates dysfunctional mitochondria and permits their removal by autophagy (Twig et al., 2008). *PINK1* loss-of-function decreases mitochondrial membrane potential (Chu, 2010) and the *PINK1*-parkin pathway is associated with mitochondrial elimination in cultured cells treated with the mitochondrial uncoupler carbonyl cyanide *m*-chlorophenylhydrazone (CCCP), which causes mitochondrial depolarization (Geisler et al., 2010; Kawajiri et al., 2010; Matsuda et al., 2010; Narendra et al., 2008, 2010; Vives-Bauza et al., 2010). However, the exact mechanism underlying the mitochondrial depolarization induced by *PINK1* defects leading to mitochondrial autophagy has not been examined in detail.

Abbreviations: $\Delta\psi$, mitochondrial membrane potential; FCCP, carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone; MEFs, mouse embryonic fibroblasts; PD, Parkinson's disease; *PINK1*, *PTEN*-induced putative kinase 1; ROS, reactive oxygen species; TMRM, tetramethylrhodamine methyl ester; TPMP, triphenylmethylphosphonium.

Here, we describe a detailed characterization of mitochondria in PINK1-deficient cells. We show that PINK1 deficiency causes a decrease in mitochondrial membrane potential, which is not due to proton leak, but to respiratory chain defects.

Materials and methods

PINK1 knock-out mouse embryonic fibroblasts (MEFs)

PINK1 knock-out MEFs were prepared and cultured as described previously (Matsuda et al., 2010). Mouse embryonic fibroblasts (MEFs) were derived from E12.5 embryos containing littermate 4 mice of each genotype. Embryos were mechanically dispersed by repeated passage through a P1000 pipette tip and plated with MEF media containing DME, 10% FCS, 1× nonessential amino acids, 1 mM L-glutamine, penicillin/streptomycin (invitrogen). The ψ 2 cell line, an ecotropic retrovirus packaging cell line, was maintained in Dulbecco's modified Eagle medium (DMEM, Sigma) with 5% fetal bovine serum and 50 μ g/ml kanamycin. Transfection of the ψ 2 cells with pMESVTS plasmids containing an SV40 large T antigen was performed by lipofection method according to the manual provided by the manufacturer (GIBCO BRL). Five micrograms of the plasmids was used for each transfection. Transfectants were selected by G418 at the concentration of 0.5 mg/ml, and 10 clonal cell lines were established. The highest titer of 5×10^4 cfu/ml was obtained for the conditioned medium of a cell line designated ψ 2SVTS1. 10^6 MEFs were plated onto a 10-cm culture dish and kept at 33 °C for 48 hours. Then medium was replaced with 2 ml supplemented with polybrene-supplemented medium conditioned by the ψ 2SVTS1 cells at confluency for 3 days. Infection was continued for 3 hours, and the medium was replaced with a fresh one. The infected MEFs were cultured at 33 °C until immortalized cells were obtained.

We confirmed that the differences we detected in this study were due to the PINK1 deficiency, not to artificial effects by immortalization, by measuring cellular respiration rates of not immortalized MEFs from other littermates (Supplemental figure). The respiration rates of not immortalized MEFs were slightly slower than those of immortalized MEFs, but the differences between PINK1^{+/+} and ^{-/-} MEFs were consistent (Fig. 2A).

Cell growth

Cells were seeded in 12-well plates at density of $3\text{--}6 \times 10^3$ cells/well and incubated in DMEM high glucose medium (4.5 g/l glucose and 1 mM sodium pyruvate) supplemented with 10% fetal bovine serum. After a day, the medium was replaced with DMEM glucose-free medium supplemented with 1 g/l galactose, 1 mM sodium pyruvate and 10% fetal bovine serum (DMEM galactose medium) at 37 °C in an incubator with a humidified atmosphere of 5% CO₂. Cells were trypsinized and live cells were assessed by trypan blue dye exclusion.

Mitochondrial morphological changes

Cells were seeded in 6-well plates at 2.0×10^5 /well and incubated in DMEM high glucose medium (4.5 g/l glucose and 1 mM sodium pyruvate) supplemented with 10% fetal bovine serum and 1% penicillin/streptomycin. After a day, the medium was replaced with DMEM glucose-free medium supplemented with 1 g/l galactose, 1 mM sodium pyruvate and 10% fetal bovine serum (DMEM galactose medium) at 37 °C in an incubator with a humidified atmosphere of 5% CO₂. 24 hours later, cells were fixed and immunostained with anti-Tom20 antibody to visualize mitochondria according to a protocol as previously described (Kawajiri et al., 2010). All images were obtained using an Axioplan 2 imaging microscope (Carl Zeiss, Oberkochen, Germany).

Cellular ATP levels

Intracellular ATP levels were determined by a cellular ATP assay kit (TOYO B-Net, Tokyo, Japan) according to the manufacturer's instructions using a Lumat LB9507 luminometer (Berthold Technology, Bad Wildbad, Germany).

Membrane potential

Fluorescence images were recorded using a multi-dimensional imaging workstation (AS MDW, Leica Microsystems, Wetzlar, Germany) with a climate chamber maintained at 37 °C. Fluorescence was quantified with a CCD camera (CoolSnap HQ, Roper Scientific, Princeton, NJ) using a 20× objective. Cells were stained for 1 hour with a non-quenching concentration (20 nM) of tetramethylrhodamine methyl ester (TMRM) in a 96-well plate. The cell-permeable cationic dye TMRM accumulates in mitochondria according to the Nernst equation. Nuclei were stained with 250 nM Hoechst 34580. Mitochondrial TMRM fluorescence was integrated in a 40- μ m diameter circular area around the nucleus, and the minimum fluorescence in this area was subtracted as background fluorescence.

Cell respiration

Cell respiration was measured at 37 °C using the Oxygen Meter Model 781 and the Mitocell MT200 closed respiratory chamber (Strathkelvin Instruments, North Lanarkshire, United Kingdom). Cells were cultured in DMEM with 4.5 g/l of glucose supplemented with 10% FBS. Cells were then trypsinized and resuspended in Leibovitz's L-15 medium (Invitrogen) at density of 8.0×10^6 cells/ml. The oxygen respiration rate was measured under each of the following three conditions: basal rate (no additions); State 4 (no ATP synthesis) [after addition of 1 μ g/ml oligomycin (Sigma)], uncoupled [after addition of 3 μ M FCCP (carbonyl cyanide *p*-trifluoromethoxyphenylhydrazone; Sigma)] using Strathkelvin 949 Oxygen System. After sequential measurements, the endogenous respiration rate was determined by adding 1 μ M rotenone + 2 μ M myxothiazol.

Mitochondrial respiration and membrane potential

Mitochondria were prepared from cultured MEFs as previously described (Amo and Brand, 2007). Mitochondrial oxygen consumption with 5 mM succinate as a respiratory substrate was measured at 37 °C using a Clark electrode (Rank Brothers, Cambridge, United Kingdom) calibrated with air-saturated respiration buffer comprising 0.115 M KCl, 10 mM KH₂PO₄, 3 mM HEPES (pH 7.2), 2 mM MgCl₂, 1 mM EGTA and 0.3% (w/v) defatted BSA, assumed to contain 406 nmol atomic oxygen/ml (Reynafarje et al., 1985). Mitochondrial membrane potential ($\Delta\psi$) was measured simultaneously with respiratory activity using an electrode sensitive to the lipophilic cation TPMP⁺ (triphenylmethylphosphonium) (Brand, 1995). Mitochondria were incubated at 0.5 mg/ml in the presence of 80 ng/ml nigericin (to collapse the pH gradient so that the proton motive force was expressed exclusively as $\Delta\psi$) and 2 μ M rotenone (to inhibit complex I). The TPMP⁺-sensitive electrode was calibrated with sequential additions of TPMP⁺ up to 2 μ M, then 5 mM succinate was added to initiate respiration. Experiments were terminated with 2 μ M FCCP, allowing correction for any small baseline drift. $\Delta\psi$ was calculated from the distribution of TPMP⁺ across the mitochondrial inner membrane using a binding correction factor of 0.35 mg protein/ μ l. Respiratory rates with 4 mM pyruvate + 1 mM malate as a substrate in State 3 (with 0.25 mM ADP) and State 4 (with 1 μ g/ml oligomycin) were determined using the Oxygen Meter Model 781 and the Mitocell MT200 closed respiratory chamber (Strathkelvin Instruments).

Modular kinetic analysis

To investigate differences in oxidative phosphorylation caused by PINK1 knock-out, we applied a systems approach, namely modular kinetic analysis (Amo and Brand, 2007; Brand, 1990). This analyzes the kinetics of the whole of oxidative phosphorylation divided into three modules connected by their common substrate or product, $\Delta\psi$. The modules are (i) the reactions that produce $\Delta\psi$, consisting of the substrate translocases, dehydrogenases and other enzymes and the components of the respiratory chain, called 'substrate oxidation'; (ii) the reactions that consume $\Delta\psi$ and synthesize, export and dephosphorylate ATP, consisting of ATP synthase, the phosphate and adenine nucleotide translocases and any ATPases that may be present, called the 'phosphorylating system'; and (iii) the reactions that consume $\Delta\psi$ without ATP synthesis, called the 'proton leak' (Brand, 1990). The analysis reports changes anywhere within oxidative phosphorylation that are functionally important but is unresponsive to changes that have no functional consequences. Comparison of the kinetic responses of each of the three modules to $\Delta\psi$ obtained using mitochondria isolated from PINK1^{+/+} and PINK1^{-/-} MEFs would reveal any effects of PINK1 on the kinetics of oxidative phosphorylation. Oxygen consumption and $\Delta\psi$ were measured simultaneously using mitochondria incubated with 80 ng/ml nigericin and 4 μ M rotenone. Respiration was initiated by 5 mM succinate. The kinetic behavior of a ' $\Delta\psi$ -producer' can be established by specific modulation of a $\Delta\psi$ -consumer and the kinetics of a consumer can be established by specific modulation of a $\Delta\psi$ -producer (Brand, 1998). To measure the kinetic response of proton leak to $\Delta\psi$, the State 4 (non-phosphorylating) respiration of mitochondria in the presence of oligomycin (0.8 μ g/ml; to prevent any residual ATP synthesis), which was used solely to drive the proton leak, was titrated with malonate (up to 8 mM). In a similar way, State 4 respiration was titrated by FCCP (up to 1 μ M) for measurement of the kinetic response of substrate oxidation to $\Delta\psi$. State 3 (maximal rate of ATP synthesis) was obtained by addition of excess ADP (1 mM). Titration of State 3 respiration with malonate (up to 1.1 mM) allowed measurement of the kinetics of the $\Delta\psi$ -consumers (the sum of the phosphorylating system and proton leak). The coupling efficiencies of oxidative phosphorylation were calculated from the kinetic curves as the percentage of mitochondrial respiration rate at a given $\Delta\psi$ that was used for ATP synthesis and was therefore inhibited by oligomycin. Note that any slip reactions will appear as proton leak in this analysis (Brand et al., 1994).

Mitochondrial ROS production

Mitochondrial ROS production rate was assessed by measurement of H₂O₂ generation rate, determined fluorometrically by measurement of oxidation of Amplex Red to fluorescent resorufin coupled to the enzymatic reduction of H₂O₂ by horseradish peroxidase using a spectrofluorometer RF-5300PC (Shimadzu, Kyoto, Japan). The H₂O₂ generation rate was measured in non-phosphorylating conditions (= State 4) using either pyruvate/malate or succinate as respiratory substrates. Mitochondria were incubated at 0.1 mg/ml in respiration buffer. All incubations also contained 5 μ M Amplex Red, 2 U/ml horseradish peroxidase and 8 U/ml superoxide dismutase. The reaction was initiated by addition of 5 mM succinate or 4 mM pyruvate + 1 mM malonate and the increase in fluorescence was followed at excitation and emission wavelengths of 560 and 590 nm, respectively. Appropriate correction for background signals and standard curves generated using known amounts of H₂O₂ were used to calculate the rate of H₂O₂ production in nmol/min/mg mitochondrial protein. The percentage free radical leak, which is a measure of the number of electrons that produce superoxide (and subsequently H₂O₂) compared with the total number of electrons which pass through the respiratory chain, was calculated as the rate of H₂O₂ production divided by the rate of O₂ consumption (Barja et al., 1994).

Statistics

Values are presented as means \pm SEM except Fig. 2D, in which error bars indicate SD. The significance of differences between means was assessed by the unpaired Student's *t*-test using Microsoft Excel; *P* values <0.05 were taken to be significant.

Results

Cell growth and mitochondrial morphology

In general, cultured cells gain their energy mostly from glycolysis. Therefore, cells deficient in respiratory function can grow in normal medium, although possibly at a slower rate, relying predominantly on glycolysis (Hofhaus et al., 1996). Actually, ρ^0 cells, which lack mitochondrial DNA completely, can grow producing energy exclusively through glycolysis (King and Attardi, 1989). On the other hand, galactose metabolism via glycolysis is much slower than glucose metabolism (Reitzer et al., 1979). Therefore, cells in galactose medium are forced to oxidize pyruvate through the mitochondrial respiratory chain for energy required for growth. Consequently, cells with defects in their mitochondrial respiratory chains show growth impairments in galactose medium. To evaluate this phenomenon is also observed in our cells, we examined growth retardation by addition of mitochondrial complex I inhibitor, rotenone (Fig. 1A). In glucose medium, 10 nM rotenone had only a slight effect on the growth of PINK1^{+/+} MEFs and slower growth was observed even in the presence of 100 nM rotenone. However, in the galactose medium, 10 nM rotenone significantly inhibited the growth of PINK1^{+/+} MEFs and 100 nM rotenone completely arrested the growth. Therefore, we could confirm that the growth impairment of our cells in the galactose medium was due to mitochondrial respiratory chain defects.

PINK1 acts upstream of parkin, regulating mitochondrial integrity and function; therefore, loss of PINK1 is considered to affect mitochondrial functions. To assess the mitochondrial functions of PINK1^{-/-} MEFs, growth capability in a medium in which galactose replaced glucose was examined. As shown in Fig. 1B, PINK1^{-/-} MEFs appeared to show clear growth impairments in the galactose medium, whereas PINK1^{+/+} MEFs grew slightly slower than in the glucose medium.

No differences of mitochondrial morphology between PINK1^{+/+} and ^{-/-} MEFs in the glucose medium were detected (Fig. 1C), consistent with the previous report (Matsuda et al., 2010). However, in the galactose medium, mitochondria of the PINK1^{-/-} MEFs were more fragmented compared to the PINK1^{+/+} MEFs (Fig. 1C). This is consistent with previous reports, which found mitochondrial morphological changes were more pronounced when PINK1 knock-down HeLa cells were grown in low-glucose medium (Exner et al., 2007) and human PINK1 homozygous mutant fibroblast in galactose medium (Grünwald et al., 2009). In these cells, mitochondrial morphological changes were associated with the mitochondrial functional impairment.

Assessments of mitochondrial functions at the cellular level

Because PINK1^{-/-} MEFs showed severe growth impairments in the galactose medium, the mitochondrial functions of these cells were assessed at the cellular level. First, cellular respiration rates were measured (Fig. 2A). The basal respiration rate was significantly reduced in PINK1^{-/-} cells compared with that in PINK1^{+/+} cells (11.13 \pm 0.71 versus 14.36 \pm 1.01 nmol O₂/min/10⁶ cells; *p* < 0.05; *n* = 5 independent experiments), consistent with previous reports using partial knock-down of PINK1 expression (Gandhi et al., 2009; Liu et al., 2009). Oligomycin inhibits ATP synthase, resulting in non-phosphorylating respiration. FCCP uncouples oxidative phosphorylation, leading to maximum respiration rates. In both conditions, the

Cells grown in 12-well plates were trypsinized and live cells were assessed by trypan blue dye exclusion. (C) Mitochondrial morphology of PINK1^{+/+} and PINK1^{-/-} MEFs. After incubating cells with the glucose or galactose medium for 24 hours, cells were fixed and immunostained with anti-Tom20 antibody to visualize mitochondria. Scale bar, 20 μm.

PINK1^{-/-} cells respired significantly slower than the PINK1^{+/+} cells (1.76 ± 0.13 versus 2.95 ± 0.27 ($p < 0.01$; $n = 5$ independent experiments) and 16.44 ± 1.80 versus 23.50 ± 1.18 nmol O/min/10⁶ cells ($p < 0.05$; $n = 5$ independent experiments), respectively).

The main function of mitochondria is ATP synthesis via oxidative phosphorylation. ATP levels under basal conditions were significantly reduced in PINK1^{-/-} MEFs (Fig. 2B), as reported previously for dissociated PINK1^{-/-} mouse neurons (Gispert et al., 2009) and PINK1

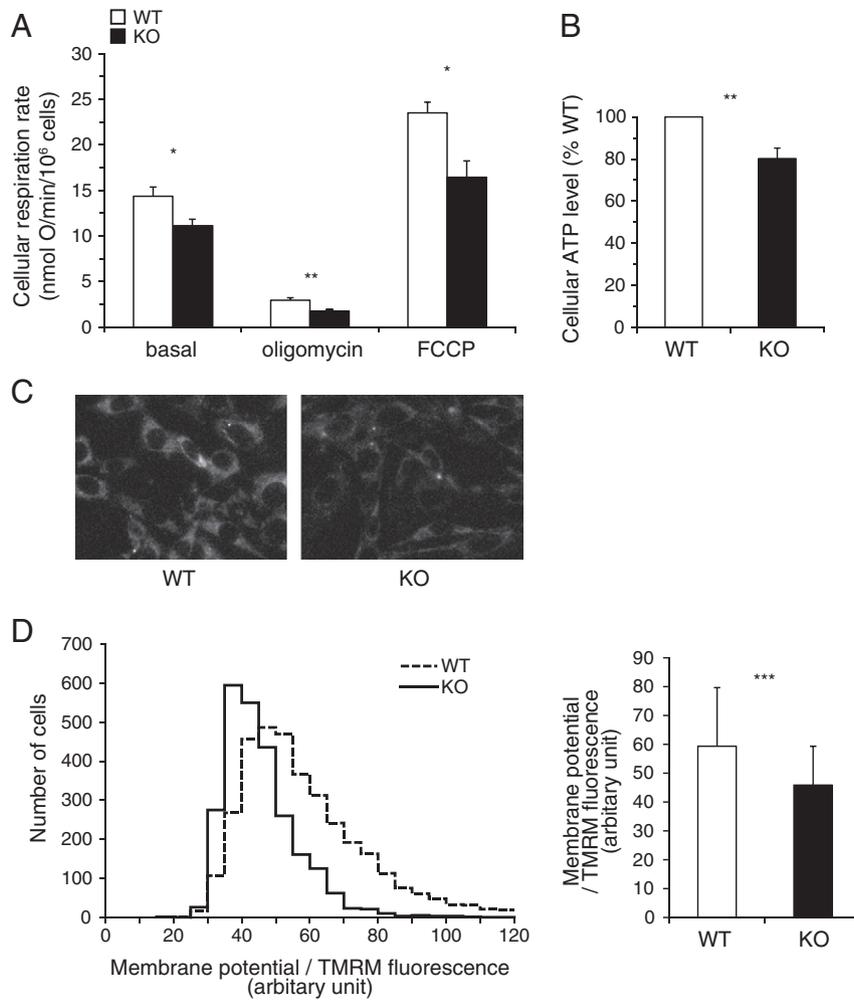

Fig. 2. Mitochondrial functions assessed at the cellular level. Open bars, PINK1^{+/+} MEFs; closed bars, PINK1^{-/-} MEFs. (A) Cell respiration rate of PINK1^{+/+} and ^{-/-} MEFs. The oxygen respiration rate was measured at density of 8.0×10^6 cells/ml under each of the following three conditions: basal rate (no additions); State 4 (no ATP synthesis) [after addition of 1 μ g/ml oligomycin], uncoupled [after addition of 3 μ M FCCP]. After sequential measurements, the endogenous respiration rate was determined by adding 1 μ M rotenone + 2 μ M myxothiazol. Error bars indicate SEM ($n = 5$ independent experiments). (B) Cellular ATP levels. Data were normalized based on cell numbers and expressed as the percentage of the level in PINK1^{+/+} cells. Error bars indicate SEM ($n = 4$ independent experiments). (C) Live cell images of PINK1^{+/+} and ^{-/-} MEFs with TMRM fluorescence. (D) Mitochondrial membrane potential evaluated by live cell imaging of TMRM fluorescence. *Left panel*, the distribution of TMRM fluorescence from 3537 PINK1^{+/+} and 2566 PINK1^{-/-} cells from 12 wells per cell type; *right panel*, the average value of TMRM fluorescence per cell. Error bars indicate SD. * $P < 0.05$; ** $P < 0.01$; *** $P < 0.001$.

siRNA knock-down PC12 cells (Liu et al., 2009). Mitochondrial membrane potential was also measured by live cell imaging of TMRM fluorescence. Typical images were shown in Fig. 2C. The histogram shows the distribution of TMRM fluorescence from 3537 PINK1^{+/+} cells and 2566 PINK1^{-/-} cells from 12 wells per cell type and the bar graph indicates the mean \pm SD of TMRM fluorescence per cell (Fig. 2D). According to the Nernst equation, the ratio of TMRM fluorescence would translate into, on average, 6.88 mV lower mitochondrial membrane potential in the PINK1^{-/-} cells if the plasma membrane potentials were not different between PINK1^{+/+} and ^{-/-} cells. Mitochondrial membrane potential decrease was also showed previously in PINK1 knock-down HeLa cells (Exner et al., 2007) and in stable PINK1 knock-down neuroblastoma cell lines (Sandebring et al., 2009).

Assessments of mitochondrial functions using isolated mitochondria

To further analyze mitochondrial functions, we measured the kinetics of oxidative phosphorylation using isolated mitochondria from PINK1^{+/+} and ^{-/-} MEFs. Fig. 3 shows the kinetics of the three modules of oxidative phosphorylation using succinate as a respiratory substrate (complex II-linked respiration). Fig. 3A shows the kinetic response of substrate oxidation to its product, $\Delta\psi$. The

substrate oxidation kinetic curve for PINK1^{-/-} cells was clearly shifted lower compared with that for PINK1^{+/+} cells, indicating that the loss of PINK1 caused mitochondrial respiratory chain defects. Fig. 3B shows the kinetic response of proton leak to its driving force, $\Delta\psi$, and Fig. 3C shows the kinetic response of the ATP phosphorylating pathway to its driving force, $\Delta\psi$. Both kinetic curves for PINK1^{+/+} and ^{-/-} MEFs (open and closed symbols, respectively) were overlapping, implying that there were no significant differences in those modules.

We also independently measured the mitochondrial oxygen consumption rate using pyruvate/malate as a respiratory substrate instead of succinate to check complex I. Modular kinetic analysis using pyruvate/malate is technically difficult for the following reasons: (1) the oxygen consumption rate with pyruvate/malate is much slower than succinate respiration; and (2) there are no competitive inhibitors of complex I-linked respiration, such as malonate for succinate respiration. As shown in Fig. 4A, the respiration rates in State 3 and 4 with pyruvate/malate of isolated mitochondria from PINK1^{-/-} cells (closed symbols) were significantly slower than those of PINK1^{+/+} cells (open symbols), as in the case of succinate respiration (Fig. 4B; data derived from the kinetic curves in Fig. 3).

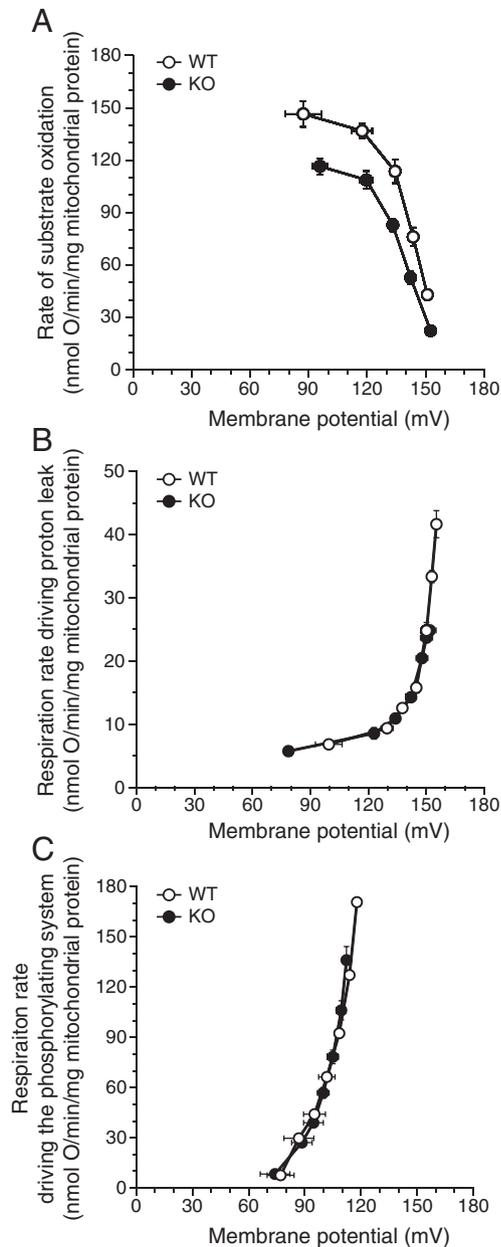

Fig. 3. Modular kinetic analysis of oxidative phosphorylation in mitochondria isolated from PINK1^{+/+} and ^{-/-} MEFs. Modular kinetic analysis of the kinetic responses to membrane potential, $\Delta\psi$, of respiration driving (A) substrate oxidation ($\Delta\psi$ titrated with uncoupler, FCCP, starting in State 4), (B) proton leak ($\Delta\psi$ titrated with malonate, starting in State 4) and (C) the phosphorylating system, calculated by subtracting respiration driving proton leak from respiration driving the $\Delta\psi$ -consumers ($\Delta\psi$ titrated with malonate starting in State 3; not shown) at each $\Delta\psi$. Open symbols, PINK1^{+/+} MEFs; closed symbols, PINK1^{-/-} MEFs. Error bars indicate SEM ($n=4$ independent mitochondrial preparations).

Mitochondrial ROS production

Mitochondrial ROS production rate was assessed by measurement of the H₂O₂ generation rate. Mechanisms of mitochondrial ROS production were well described elsewhere (Fig. 1 of Lambert et al., 2010). Pyruvate and malate generate NADH, which induced forward electron transport and generate ROS mainly from complex I and III. For pyruvate/malate respiration, the basal H₂O₂ generation rate (measured in the absence of respiratory chain inhibitors) was not different between PINK1^{+/+} and ^{-/-} mitochondria (Fig. 4C). The addition of antimycin A and further addition of rotenone, which inhibited forward electron transport at complex III and I, respectively,

enhanced H₂O₂ generation. During succinate respiration in the absence of respiratory chain inhibitors, ROS are generated mainly from the quinone binding site of complex I due to reverse electron flow from coenzyme Q to complex I. For succinate respiration, H₂O₂ generation rate in the absence of respiratory chain inhibitors was higher in PINK1^{+/+} mitochondria than in PINK1^{-/-} mitochondria, but the difference was not significant (Fig. 4D). The addition of rotenone, which blocks reverse electron flow from coenzyme Q to complex I, attenuated H₂O₂ generation.

Figs. 4C and D show a tendency for PINK1^{+/+} mitochondria to generate more ROS than PINK1^{-/-} mitochondria. However, their respiration rates were remarkably different (Figs. 4A and B). Therefore, we calculated the percentage free radical leak, which is the fraction of molecules of O₂ consumed that give rise to H₂O₂ release by mitochondria (free radical leak) during either pyruvate/malate or succinate State 4 respiration (Figs. 4E and F). For pyruvate/malate respiration, mitochondria isolated from PINK1^{-/-} cells had higher proportion of H₂O₂ generation than PINK1^{+/+} mitochondria. During succinate respiration without respiratory inhibitors, PINK1^{-/-} mitochondria had also higher proportion of free radical leak mainly from complex I due to reverse electron flow from coenzyme Q to complex I. Because the differences disappeared with addition of rotenone, which inhibit reverse electron flow, ROS generation enhanced by loss of PINK1 was mostly from complex I.

Discussion

We produced an *in vitro* model of Parkinson's disease, immortalized PINK1^{-/-} MEFs. Previously, impairment of mitochondrial respiration was observed in the brains of PINK1^{-/-} mice (Gautier et al., 2008). PINK1^{-/-} MEFs clearly showed a phenotype of mitochondrial dysfunctions, which is consistent with PD pathogenesis. This phenotype was apparent in a cell growth experiment using medium containing galactose instead of glucose (Fig. 1B). Mitochondrial fragmentation was observed when PINK1^{-/-} MEFs grew in the galactose medium (Fig. 1C), which was consistent with previous reports (Exner et al., 2007; Grunewald et al., 2009). Our results have unveiled that the PINK1^{-/-} MEF line could be a potential PD model, presenting growth retardation due to decreased mitochondrial respiration activity. Thus, the PINK1^{-/-} MEFs are a useful tool for evaluating the role of PINK1 in mitochondrial dysfunction and relevant to PD.

In PINK1^{-/-} MEFs, mitochondrial membrane potential was decreased compared with that in littermate wild-type MEFs (Figs. 2C and D), as reported previously for PINK1 knock-down HeLa cells (Exner et al., 2007) and stable PINK1 knock-down neuroblastoma cell lines (Sandebring et al., 2009). This is a key event during elimination of mitochondria. Mitochondrial fission followed by selective fusion segregates damaged mitochondria, which decreases their membrane potential, and permits their removal by autophagy (Twig et al., 2008). The PINK1-parkin pathway is thought to have a crucial role in this mitochondrial elimination mechanism (Geisler et al., 2010; Kawajiri et al., 2010; Matsuda et al., 2010; Narendra et al., 2008, 2010; Vives-Bauza et al., 2010). To clarify what caused the decrease in mitochondrial membrane potential, we performed a modular kinetic analysis using isolated mitochondria (Fig. 3). This analyzes the kinetics of the whole of oxidative phosphorylation divided into three modules connected by their common substrate or product, mitochondrial membrane potential ($\Delta\psi$). The modules include one $\Delta\psi$ -producer (substrate oxidation) and two $\Delta\psi$ -consumers (phosphorylating system and proton leak) (Brand, 1990). To decrease $\Delta\psi$, the $\Delta\psi$ -producer should be down-regulated and/or $\Delta\psi$ -consumers should be up-regulated. As cellular ATP levels were decreased compared with those in littermate wild-type MEFs (Fig. 2B), it is unlikely that the phosphorylating system is up-regulated. Indeed, the kinetics of the phosphorylation module were not altered (Fig. 3C). The other $\Delta\psi$ -consumer, proton leak,

(A) State 3 and State 4 respiration rate of mitochondria with pyruvate/malate as a respiratory substrate. (B) State 3 and State 4 respiration rate of mitochondria with succinate as a respiratory substrate. Data were derived from the results of modular kinetic analysis (Fig. 3). State 3 respiration rates were the kinetic start points of the $\Delta\psi$ -consumers (the sum of the phosphorylating system and proton leak). State 4 respiration rates were average values of the respiration rates at the kinetic start points of substrate oxidation and proton leak. (C, D) Mitochondrial H₂O₂ production rate with pyruvate/malate (C) or succinate (D) as a respiratory substrate. (E, F) Percentage free radical leak (FRL) for State 4 respiration with pyruvate/malate (E) or succinate (F) as a respiratory substrate. Error bars indicate SEM ($n = 5$ and 4 independent mitochondrial preparations for pyruvate/malate and succinate respiration, respectively). * $P < 0.05$; ** $P < 0.01$; *** $P < 0.001$.

which partially dissipates the membrane potential without ATP synthesis, was also not changed (Fig. 3B). Therefore, the decrease in membrane potential caused by loss of PINK1 is likely to have been caused only by lower activity of the $\Delta\psi$ -producer, substrate oxidation (Fig. 3A). This is the first report showing that mitochondrial membrane potential decrease caused by loss of PINK1, which is the key event for the following mitochondrial elimination, was not due to proton leak, but to respiratory chain defects. We used only succinate (a complex II-linked substrate) as a respiratory substrate in the modular kinetic analysis for technical reasons. However, complex I-linked respiration (pyruvate/malate) was also decreased in PINK1^{-/-} MEFs like succinate respiration (Fig. 4A).

The mitochondrial respiration rates in State 4 were decreased in PINK1^{-/-} MEFs, and consequently, the proportions of free radical leak were significantly higher in PINK1^{-/-} MEFs than in PINK1^{+/+}

MEFs (Figs. 4E and F). Because the differences disappeared with addition of rotenone (complex I inhibitor, which inhibits reverse electron flow from coenzyme Q to complex I), ROS generation enhanced by loss of PINK1 was mostly from complex I. These results are partially consistent with those in previous reports, suggesting that MPTP and rotenone induce neuronal cell death by inhibiting complex I activity, leading to a PD-like phenotype (Dauer and Przedborski, 2003; Jackson-Lewis and Przedborski, 2007; Trojanowski, 2003).

In this study, we developed an *in vitro* PD model, the PINK1^{-/-} MEF line, and established the experimental conditions for cell growth to detect mitochondrial dysfunction. This is the first report showing that complete ablation of PINK1 causes a decrease in mitochondrial membrane potential, which is not due to proton leak, but to respiratory chain defects.
